comparative analysis

Assignment help

- Your solution will require classes to represent a GA individual, the population, and the ordered crossover
~~Assignment (Project Exam Help)~~
- It also needs ~~rcle placement~~ algorithm (B <https://eduassistpro.github.io/>). You should not need to make ~~Add WeChat edu_assist_pro~~ changes to this code...
- The main application should create a *Bunch* object for *each* of the three algorithms – this allows you to easily display all three

Assignment help

- Your Bunch class should contain a geneticPlace() method, which takes in all of the parameters of the GA (that is, it should be entirely self-contained)
Assignment Project Exam Help
- It will be *much* more successful if you have already successfully implemented the selection class (as in a previous lab).
Add WeChat edu_assist_pro
- Given that we are using an ordering encoding, it's no surprise than an individual's genome should be a list of integers – the ordering of the set of circles
- That is, a genome of “21345”, specifies circle 2 to be placed first, followed by 1, 3, 4, then 5

Assignment help

- When evaluating an individual's genome in the fitness function, you should realise that you can actually reuse the `orderedPlace()` method that we have already encountered
- You can *override* <https://eduassistpro.github.io/> a version that *takes in* a *list* of integers...) and places them in order
- The fitness function in my `Individual` class is *extremely short*; it simply creates a temporary `Bunch` of circles, orders them according to the genome, calls the method to compute the boundary, and then returns this as the fitness...

Assignment help

- When doing a *comparative analysis* of your genetic algorithm (i.e., comparing with greedy search), it is important to specify the parameters used, and investigate th **Assignment Project Exam Help** (see previous lecture) <https://eduassistpro.github.io/>
- Also, it is important to perfo **Add WeChat edu_assist_pro** runs of your GA, and then take the *averag* es found, in order to ensure that you get a representative sample
- How many runs is “enough”? – probably around 30-50
- It is also interesting to plot the *convergence* of your algorithm over time

Encodings

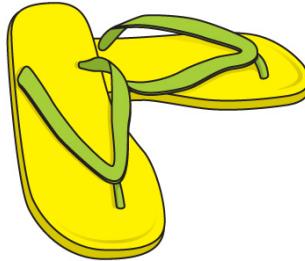

- How we *encode* a solution to our problem is also vital to the success of the GA
- Ideally, our encoding will be expressed as a linear *string* <https://eduassistpro.github.io/> such as characters, i [Add WeChat edu_assist_pro](#)
- An encoding might *directly* sent the objects that are evolving (e.g. strings of text), or *indirectly* represent the presence or absence of objects with certain attributes

Indirect encoding example

- Consider the following problem: we wish to pack for our holiday, and we have a suitcase with a specific capacity (luggage weight limit)
Assignment Project Exam Help
- We have a [f](https://eduassistpro.github.io/), which has a *weight* and *utility*. How useful is it?
Add WeChat edu_assist_pro
- We wish to find the *set of items* that maximises our utility, whilst staying within the weight limit

Utility: 8
Weight: 4

Utility: 5
Weight: 5

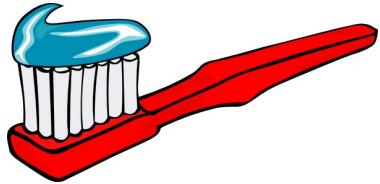

Utility: 9
Weight: 7

Capacity: 15 Utility: 10 Weight: 5

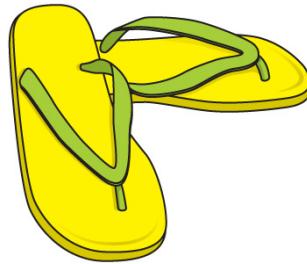

How do we encode a solution to this problem?

Choosing an encoding

- We need to work out what the problem is asking of us...
- It needs us to find a subset of items, subject to certain constraints
 - That is, each “out” of the suitcase
- A solution is a *candidate* / *s*, which is then assessed according to the criteria
- In this case, if we *order* the items, a simple *binary encoding* will suffice

Utility: 8
Weight: 4

Utility: 5
Weight: 5

Utility: 9
Weight: 7

Utility: 10
Weight: 5

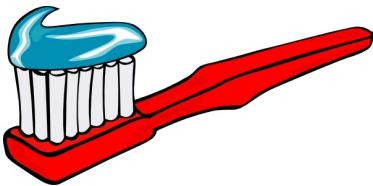

Assignment Project Exam Help

<https://eduassistpro.github.io/>

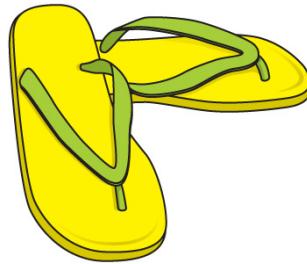

Add WeChat `edu_assist_pro`

We can now use a simple binary encoding on the ordered list of items, so 1001 represents “include toothbrush and suncream”, whilst 0111 represents “flip-flops, bikini and suncream”

Capacity: 15

Utility: 8
Weight: 4

Utility: 5
Weight: 4

Utility: 9
Weight: 7

Utility: 10
Weight: 5

<https://eduassistpro.github.io/>

We call a *sequence* the *genotype*, as it represents an individual's "genetic code". What a genotype represents or builds is called the *phenotype*, and it is this "body" that we assess or assign a fitness value to.

Total profit: 14

A genetic algorithm

We use a simple binary encoding scheme, with a binary vector $x=[x_1, \dots, x_n]$ to represent n items, where $x[i]=1$ if the item is *included* in the suitcase, and $x[i]=0$ if it is not

The fitness function for a given solution, x , is as follows:

We denote the profit of <https://eduassistpro.github.io/>

```
total weight = 0      Add WeChat / edu_assist_pro
for each item, x[i]           in suitcase
    if x[i] = 1 then add w[i] to total weight

if total weight <= total capacity
    fitness = 0
    for each item, x[i]           // add profits together
        if x[i] = 1 then add p[i] to fitness
    return fitness
else                                // over capacity
    return capacity-total weight
```

A genetic algorithm

We use a simple binary encoding scheme, with a binary vector $x=[x_1, \dots, x_n]$ to represent n items, where $x[i]=1$ if the item is *included* in the suitcase, and $x[i]=0$ if it is not

The fitness function for a given solution, x , is as follows:

We denote the profit of <https://eduassistpro.github.io/>

```
total weight = 0      Add WeChat / edu_assist_pro
for each item, x[i]
    if x[i] = 1 then add w[i] to total weight

if total weight <= total capacity
    fitness = 0
    for each item, x[i]
        if x[i] = 1 then add p[i] to fitness
    return fitness
else
    return capacity-total weight
```

Penalise “illegal” solution,
by essentially giving it a
negative fitness

// over capacity
